Workforce imperative

Political imperatives

Role of rural clinical school  
movement

**Australian Government funding for university medical places**

*Posted 25/05/2022 by Dr Hazel Ferguson*

As the gateway to the medical profession, medical schools have a role in addressing a range of issues in Australian health policy, including persistent geographical inequalities in access, and shortages in specialisations such as psychiatry.

Recent policy, including a limited redistribution of university medical places in favour of regional universities, has focused on redistributing existing resources to address chronic geographical shortages.

# A MODEL FOR COMMUNITY LEVEL IMPACT OF A RURAL CLINICAL SCHOOL -towards measurement tools

Sally Hall, Hilary Miller, Miriam Geminis, Edward Reynolds, Michelle Irving, Amanda Barnard  
Australian National University Medical School, Rural Clinical School, Canberra, Australia.

## ANU Rural Clinical School

- Embedding medical school campuses and student experiences in rural communities is a key element of rural clinical schools in Australia [1] and in community-oriented medical schools more generally [2].
- Limited research has been conducted into the impact of rural clinical schools on the social life of communities where they are located and engaged.
- The qualitative, exploratory project employed a two phase approach using focus groups, key informant interviews, participant observation and documentary analysis to describe the community-level impact of the ANU Rural Clinical School (RCS) on the host communities within its geographic footprint and to develop a theoretical model.

- We aimed to:
- describe the impact of the RCS on rural communities where teaching activities occur;
  - describe the impact of the RCS on the day to day life of the local health care system, and specifically on local services;
  - assess impact on medical student supervisors of their engagement in teaching activities; and
  - inform the development of a tool / mechanism for measuring community impact in a health care context.

## Our region

- 58 900 square kilometres (Australian Capital Territory & south eastern NSW)
- 616 000 people, 230 500 residing in rural New South Wales.
- 40 general practice training sites.
- 13 regional hospitals.
- 1 tertiary referral hospital (Canberra)

## Our program

- Four-year post-graduate MChD program, 3rd year students spent at least 8 weeks in rural clinical placements.
- Approximately 25% undertake a 12-month long integrated placement, focusing on general practice and local hospitals - the 'Rural Stream'; 26 Rural Stream doctors offered in 2015.
- Program organised around teaching / administrative nodes located in 5 sub-regions (study sites), with a central coordinating hub based at the ANU campus in Canberra.

## Aims & Methods

This project adopted a realist perspective, drawing on ethnographic methods and rapid appraisal techniques, with data collection undertaken in 2 sequential phases.

	Phase 1	Phase 2
Data Collection	<ul style="list-style-type: none"> <li>series of 8 formative focus groups</li> <li>sample = staff and students</li> <li>documentary analysis of historical local media reports (n=94, from 16 media sources)</li> </ul>	<ul style="list-style-type: none"> <li>key informant interviews and site visits</li> <li>sample = community based individuals and groups, medical and allied health professionals, and local businesses (see Table 1)</li> <li>participants selected using a targeted purpose approach with secondary recruitment of a convenience snowball sample</li> </ul>
Observation	<ul style="list-style-type: none"> <li>identify key themes and develop a working model of 'impacts' operating at the local level</li> <li>thematic coding using grounded theory approach</li> </ul>	<ul style="list-style-type: none"> <li>to explore and refine impacts and understand interactions and processes that explain the model</li> <li>coded using structure theoretical in Phase 1, with allowance for additional open coding of emergent nodes and refinement of model</li> <li>followed by secondary coding to identify relationships between thematic nodes and develop causal mechanism-outcome (CMO) configurations to inform realist synthesis.</li> </ul>
Data Analysis		

Table 2: Key informant sampling across 5 geographic sites

Sphere	Examples of Key informant groups / individuals	Number per site
Community groups	Service clubs, Disease / health related support groups, Community Advisory Board members	3
Indigenous groups	Indigenous Homework Club, Aboriginal Medical Service	2
Government services	Schools, Local Government, Corrective Services, non health related community services	3
Elderpeople	Patients, community hosts, local business, site specific contacts, community leaders	3
Private sector health services	General practice and medical specialists in private practice, Community pharmacy, Dispensaries of General Practice / Medicine Locals / PHOs.	6
Public sector health services	Ambulance and emergency services	6

This approval was provided by the ANU Human Research Ethics Committee, approved 2012/02 and 2012/03. The study was funded by the inclusion of Southern NSW Local Health District (LHD) staff. Staff in clinical settings received the RCS training separate to their official appointment.

## Results

- 102 interviews conducted with 117 respondents (response rate 72.6%), some interviewed in pairs or small groups reflecting organisational affiliations.
- Almost 36 hours of interview data, most interview times approximately 25 minutes.
- Participants evenly distributed across the health sector (1/3), community based and public sector organisations (1/3), and individual community members (1/3).

### A model of community impact

The model operates as a dynamic feedback system. When drivers are actualised they act as benefits which have an ongoing and reciprocal positive feedback effect. Costs in turn have a negative feedback effect through creating identifiable risks to sustainability.

Impacts result from both the presence of students in individual situations and more broadly as a result of the presence of the RCS and the University in local communities. RCS activity impacts differently on various community actors within different community spaces or spheres of influence.

Impacts were identified at the micro, meso and macro levels within communities, affecting individuals, specific groups and whole communities.

Individual actors were more heavily represented on the inputs side of the model, as they provide much of the time, energy and motivation to undertake specific work on behalf of the RCS, while communities and populations are more often the recipients of macro level benefits.

## Conclusions

- This qualitative investigation provides exploratory results to inform the development of survey metrics for ongoing assessment and monitoring of community impact.
- The features identified in the model provide an empirical and theoretical framework to support a comprehensive measurement approach, and are consistent with approaches such as the Theanet social accountability framework [3].
- Measurement mechanisms could be constructed from currently validated tools, existing data sources, and the development and testing of specific instruments.

# Successes

Back to this morning .....what was behind them?

Flexibility

Recognition and celebration of diversity

Connection

Generalist perspective of our leaders and clinicians

# Why the loss of generalism?

A generalist must develop the skills to	A specialist must develop the skills to
<b>Tolerate uncertainty</b> - generalists must manage a large proportion of patients with undifferentiated symptoms, including those who present early in the course of illness, those with evolving conditions, or those whose symptoms do not form a characteristic pattern of disease.	Reduce uncertainty - specialists are expected to discover a diagnosis and to investigate until this is achieved. If they are unable to identify a diagnosis within their own specialty, they are usually expected to discharge the patient or suggest referral on to another specialist, rather than manage the diagnostic uncertainty.
<b>Explore probability</b> - generalists see patients from an unscreened population with a relatively low incidence of disease. They require highly developed diagnostic skills, including recognition of common conditions and awareness of the limits of their knowledge. Their decisions are based on the epidemiology of the community and the consequent probability that the patient's symptoms are medically significant.	<b>Explore possibility</b> - specialists see a preselected population of patients with a relatively high incidence of serious disease. They require expert knowledge of the rare and esoteric conditions that are relatively more likely to be the cause of the problem in this population.
<b>Marginalise danger</b> - a key skill of a general practitioner is to recognise and act on potential dangers to patients and communities even when there is diagnostic uncertainty; this often requires referring the patient or initiating treatment before a diagnosis has been established (for example, in a case of suspected meningitis or cancer).	<b>Marginalise error</b> - a specialist must ensure that they reach an accurate diagnosis to guide treatment for the patient, in order to enable a successful outcome.
